

# Security

sebinbenjamin

# What we'll do learn today

- Why should I know about security ?
- Threats, Vulnerabilities & Attacks
- Common website threats
- Encryption & Hashing
- HTTPS, SSL & TLS

# Why security ?

The Internet is a dangerous place.

Website security is the act/practice of **protecting** websites from unauthorized access, use, modification, destruction, or disruption

We worry about security when we have something of value which is at risk of being harmed.

*Breaches and Incidents | Cyber Security News Today | Articles on Cyber Security.*

*Malware Attack updates*

*The 15 biggest data breaches of the 21st century*

# Threats, Vulnerabilities & Attacks

A **threat** source refers to an individual or entity that wishes to do us harm in our online lives.

**Vulnerabilities** are the gaps or weaknesses that undermine an organization's IT security efforts.

**Risk** refers to the calculated assessment of potential threats to an organization's security and vulnerabilities within its network and information systems.

# Common website threats

- Cross-Site Scripting (XSS)
- SQL injection
- Cross-Site Request Forgery (CSRF)
- Distributed Denial of Service
- File inclusion vulnerability

## Query components/strings

When a form containing the fields field1, field2, field3 is submitted, the content of the fields could be encoded as a *query string* as follows

field1=value1&field2=value2&field3=value3...

OR

field1=value1;field2=value2;field3=value3...

<https://example.com/over/there?name=ferret&color=purple>

*[https://en.wikipedia.org/wiki/Query\\_string](https://en.wikipedia.org/wiki/Query_string)*

*<https://stackoverflow.com/questions/39266970/what-is-the-difference-between-url-parameters-and-query-strings>*

```
inputString = '<script%20src="http://evilsite.com/tricky.js"></script>'
```

```
encodedString = encodeURIComponent(inputString);
```

```
"%3Cscript%2520src%3D%22http%3A%2F%2Fevilsite.com%2Ftricky.js%22  
%3E%3C%2Fscript%3E"
```

```
decodeURIComponent(encodedString)
```

```
'<script%20src="http://evilsite.com/tricky.js"></script>'
```

`http://mysite.com?q=beer<script  
%20src="http://evilsite.com/tric  
ky.js"></script>`

*<https://reactjs.org/docs/introducing-jsx.html#jsx-prevents-injection-attacks>*

SELECT \* FROM users WHERE email = '\$email' AND password = md5('\$password');

*Supplied values*

{ xxx@xxx.xxx

xxx') OR 1 = 1 -- ]

SELECT \* FROM users WHERE email = 'xxx@xxx.xxx' AND password = md5('xxx') OR 1 = 1 -- ]');

SELECT \* FROM users WHERE FALSE AND FALSE OR TRUE

SELECT \* FROM users WHERE FALSE OR TRUE

SELECT \* FROM users WHERE TRUE

Good engineering involves thinking about how things can be made to work;  
the *security mindset* involves thinking about *how things can be made to fail* .

A CRYPTO NERD'S  
IMAGINATION:

HIS LAPTOP'S ENCRYPTED.  
LET'S BUILD A MILLION-DOLLAR  
CLUSTER TO CRACK IT.

BLAST! OUR  
EVIL PLAN  
IS FOILED!

NO GOOD! IT'S  
4096-BIT RSA!

WHAT WOULD  
ACTUALLY HAPPEN:

HIS LAPTOP'S ENCRYPTED.  
DRUG HIM AND HIT HIM WITH  
THIS \$5 WRENCH UNTIL  
HE TELLS US THE PASSWORD.

GOT IT.

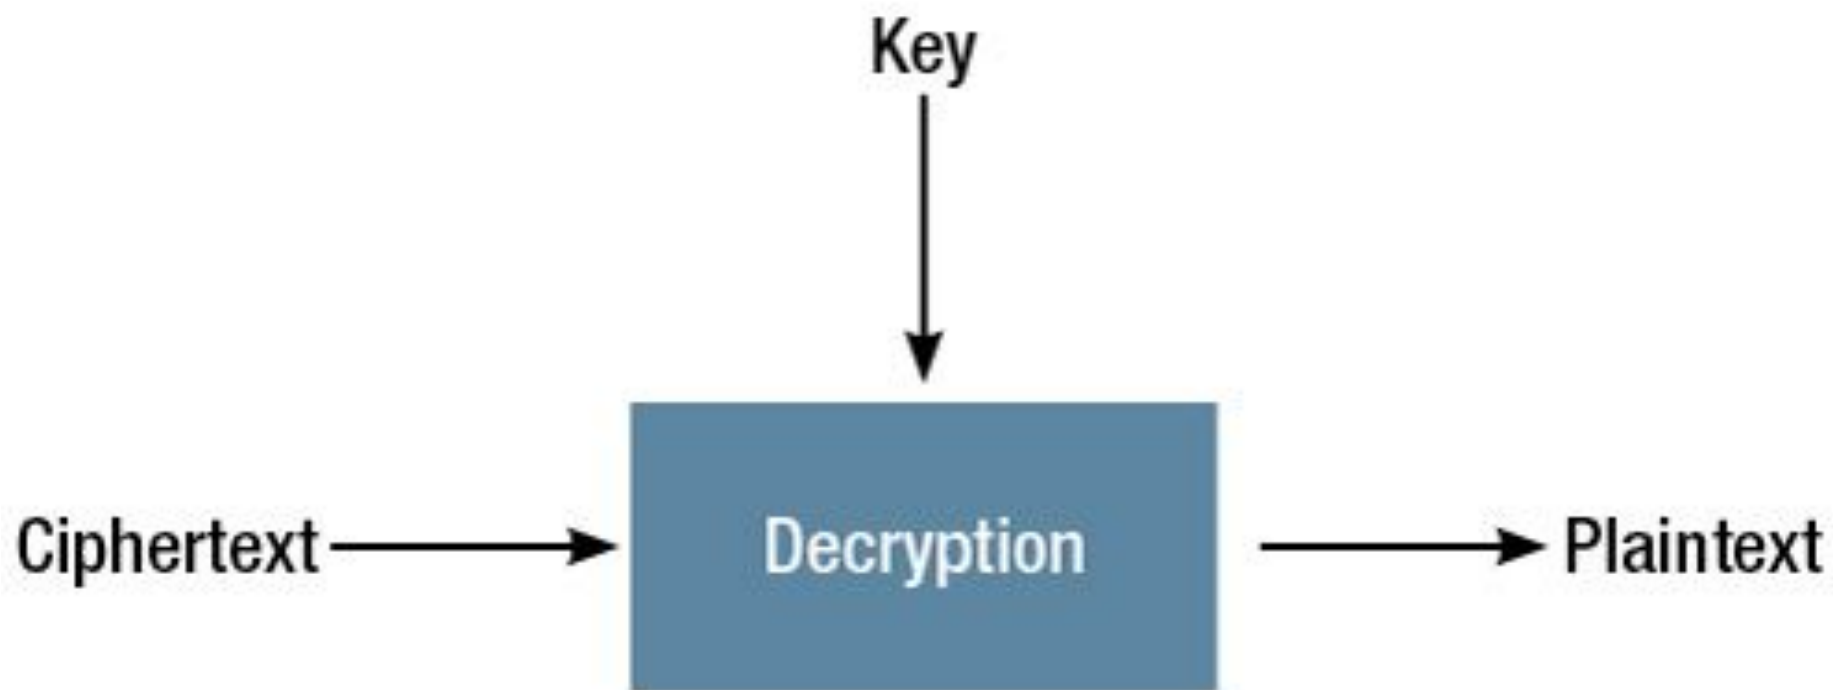

# Encryption

Encryption involves encoding data so that it can only be accessed by those who have the **key**. This protects it from unauthorized parties.

In a simplest form, **encryption** is to convert the data in some unreadable form. This helps in protecting the privacy while sending the data from sender to receiver.

On the receiver side, the data can be **decrypted** and can be brought back to its original form.

# Encryption & Decryption

Plaintext

Ciphertext

Plaintext

# The Caesar cipher

Khan Academy

# Earliest example: Ceaser Cipher

The Caesar cipher is one of the earliest known and simplest ciphers.

It is a type of substitution cipher in which *each letter in the plaintext is 'shifted'* a certain number of places down the alphabet.

The method is named after Julius Caesar, who apparently used it to communicate with his generals.

*Caesar cipher: Encode and decode online — Cryptii*

# Hashing

**Hashing** is the process of converting a given key into another value.

A ***hash function*** is used to generate the new value according to a mathematical algorithm.

The result of a hash function is known as a ***hash value*** or simply, a hash.

A good hash function uses a ***one-way hashing algorithm***, or in other words, the hash cannot be converted back into the original key.

A good hash function uses a one-way hashing algorithm, or in other words, the hash cannot be converted back into the original key.

~28 BITS OF ENTROPY

$2^{28} = 3 \text{ DAYS AT } 1000 \text{ GUESSES/SEC}$

(PLAUSIBLE ATTACK ON A WEAK REMOTE WEB SERVICE. YES, CRACKING A STOLEN HASH IS FASTER, BUT IT'S NOT WHAT THE AVERAGE USER SHOULD WORRY ABOUT.)

DIFFICULTY TO GUESS: **EASY**

WAS IT TROMBONE? NO, TROUBADOR. AND ONE OF THE 0s WAS A ZERO?

AND THERE WAS SOME SYMBOL...

DIFFICULTY TO REMEMBER: **HARD**

~44 BITS OF ENTROPY

$2^{44} = 550 \text{ YEARS AT } 1000 \text{ GUESSES/SEC}$

DIFFICULTY TO GUESS: **HARD**

THAT'S A BATTERY STAPLE.

CORRECT!

DIFFICULTY TO REMEMBER: YOU'VE ALREADY MEMORIZED IT

THROUGH 20 YEARS OF EFFORT, WE'VE SUCCESSFULLY TRAINED EVERYONE TO USE PASSWORDS THAT ARE HARD FOR HUMANS TO REMEMBER, BUT EASY FOR COMPUTERS TO GUESS.

***<https://howsecureismypassword.net/>***

# Encryption vs Hashing

Encryption is a ***two-way function***. You encrypt information with the intention of decrypting it later.

Hashing, however, is a ***one-way function***. It scrambles plain text to produce a unique message digest. An attacker who steals a file of hashed passwords must then guess the password.

How To Safely Store A Password | codahale.com

Bcrypt library node - <https://www.npmjs.com/package/bcrypt>

# HTTPS And SSL

SSL stands for “Secure Socket Layer.” It is a technology that ***establishes a secure session link*** between the visitor’s web browser and your website so that all ***communications*** transmitted through this link are ***encrypted*** and are, therefore, secure.

SSL is also used for transmitting secure email, secure files, and other forms of information.

# How Does SSL Encryption Work?

In the same way that you lock and unlock doors using a key, encryption makes use of keys to lock and unlock your information. Unless you have the right key, you will not be able to “open” the information.

Each SSL session consists of two keys:

- The ***public key*** is used to encrypt (scramble) the information.
- The ***private key*** is used to decrypt (un-scramble) the information and restore it to its original format so that it can be read.

A BROWSER REQUESTS A  
SECURE PAGE WITH HTTPS:/ & WEB SERVER  
SENDS ITS PUBLIC KEY  
WITH IT'S CERTIFICATE

BROWSER ENSURES THAT  
THE CERTIFICATE IS TRUSTED  
(UNEXPIRED, UNREVOKED)

THE BROWSER CREATES A SYMMETRIC KEY &  
SENDS IT TO THE SERVER,  
THEN SERVER DECRYPTS THAT  
SYMMETRIC KEY USING PRIVATE KEY

THE SERVER SENDS THE PAGE  
ENCRYPTED WITH  
THE SYMMETRIC KEY.

THE BROWSER DECRYPTS THE PAGE USING  
THE SYMMETRIC KEY AND  
DISPLAYS THE INFORMATION.

Secure Sockets Layer, or SSL,  
was the old standard security  
technology for *creating an  
encrypted network link*  
between a server and client,  
ensuring all data passed is  
private and secure.

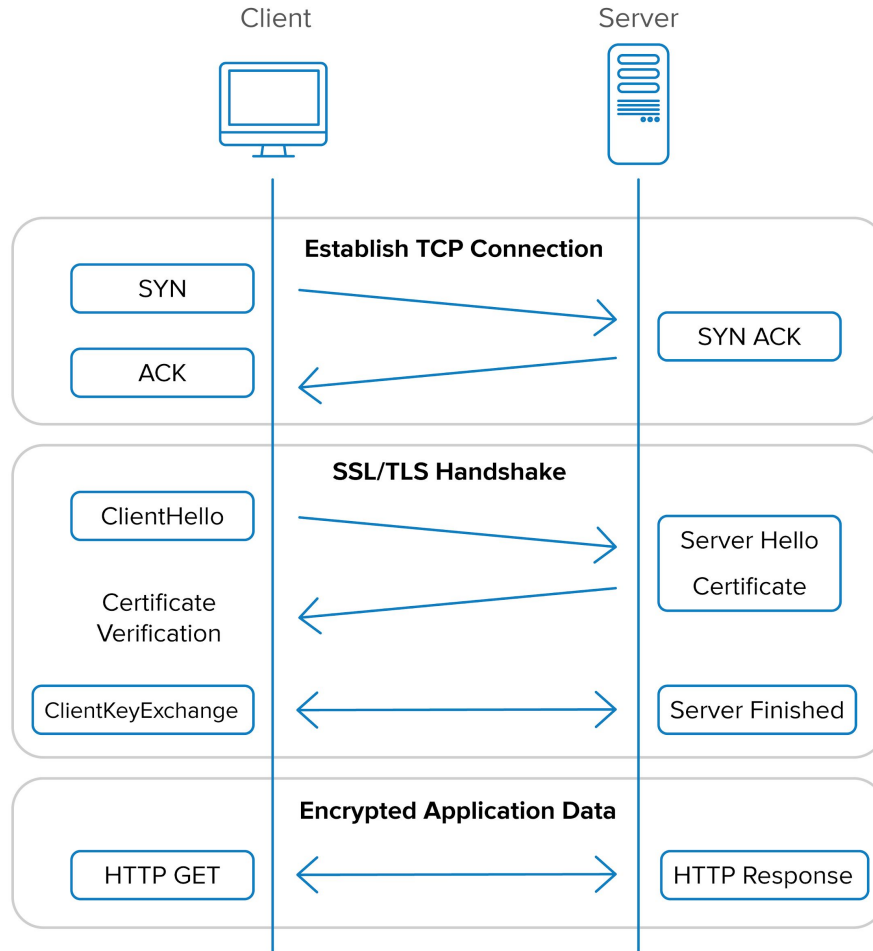

# Transport Layer Security

The Transport Layer Security (TLS) protocol is the standard for enabling two networked applications or devices to exchange information privately and robustly.

**Applications** that use TLS can *choose their security parameters*, which can have a substantial impact on the security and reliability of data.
